

How do we study atoms?

- We measure the frequency (ν) of the light that causes transitions
- The strongest transitions are usually in the visible region of the optical spectrum
- However, frequencies of visible light are very high – on the order of
400,000,000,000,000 Hz
- Modern electronics cannot count frequencies this high
- However, we can use **interference** to produce a measurable frequency

Interference
